

# 1010 Amplifier (P/N AM-0007)

## Low Noise Amplifier

### Technical Description:

The Model 1010 amplifier is a DC coupled amplifier that is compact, rugged and battery powered. The amplifier circuit and batteries are housed in a die casted aluminum case. The micro powered circuit design gives a **continuous operating life of more than one year** from the two internal batteries (included). BNC connectors are used for signal input and output connections.

The very low voltage noise and current noise in the critical low frequency region of 0.1 Hz to 10 Hz makes the Model 1010 ideal for use with thermopile detectors. To prevent accidental damage to the input transistors the input is diode protected.

1010 Amplifier

### Not Currently RoHS Compliant

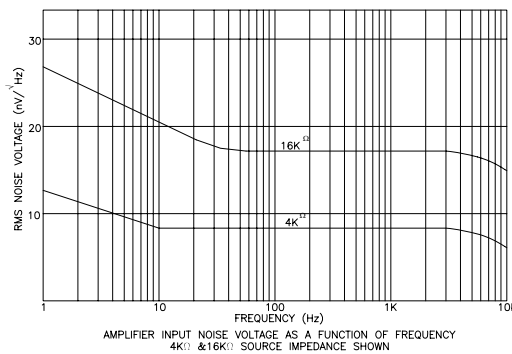

#### Features

- DC Coupled
- Low Noise
- DC offset Adjustment
- Micro Power
- 100% Electrostatic Shielding
- Battery Powered
- Gain of 1000

#### Technical Specifications

Specifications apply at 23°C

## 1010 Amplifier (P/N AM-0007)

TYPICAL MODULATED SIGNAL RECTIFIER FOR 10 Hz (Full Wave) USING 1010 AMPLIFIER  
Adjust RC circuit (C1 & R6) for modulation frequency

### Operating Instructions:

**INPUT CONNECTOR:** A shorting type BNC cap is used to protect the amplifier input. When the amplifier is not connected to an input source this cap should be reconnected to prevent draining the batteries.

**OFFSET ADJUSTMENT:** The amplifier DC offset can be adjusted with a small screwdriver through an access hole in the side of the housing. This adjustment is by means of a 22 turn cermet potentiometer. Adjust offset with detector connected. Blinded detector should be at thermal equilibrium for at least 15 minutes. Then adjust offset to your reference voltage (zero in most cases).

**BATTERY REPLACEMENT:** Remove the top cover by loosening the four screws. These screws are held captive to the cover. Replace the batteries with 9-Volt alkaline batteries. Replace cover.

**CAUTION:** Do not allow inner flange of cover to pinch the battery wires or the batteries.

# Miniature Amplifier PCB

## Applications

Facilitates fast R&D startup time that can be integrated into your prototypes or final system design.

- Non-contact Temperature measurement
- Gas analysis
- Multiplexing of a number of thermopiles
- Reduction of noise on long cables

## General Description

Available in three amplifier gains: 300, 500 and 1,000, this PCB includes a LM20 temperature sensor and 1.25V voltage reference. Although sized for single channel TO-5 packages, this amplifier is electrically compatible with all Dexter Research Center detectors, providing convenient buffering and pre-amplification of thermopile signal. The amplifier circuit board is impressively small (0.35" x 0.85") and is designed around the AD8628 amplifier with ultra low offset (<1μV), low drift (<0.005μV/°C), and low bias current (100pA). The Mini Amp will operate on a 2.7V to 5.5V single supply, is chopper stabilized and has greatly reduced digital switching noise (0.5μV<sub>p-p</sub> from 0Hz to 10Hz, input referred).

The LM20 temperature sensor (National Semiconductor) has precision analog output. The transfer function of LM20 is predominantly linear, yet has slight predictable parabolic curvature. The accuracy of the LM20 when specified to a parabolic transfer function is 1.5°C at room temperature. There is an option to connect any two terminal temperature sensor in place of LM20, for example a thermistor.

The LT1790 low drop out voltage reference combines high accuracy (0.05%) and low drift (10ppm/°C). The voltage reference has operational temperature range from -40°C to +85°C. The board may be used with an external voltage reference as well.

## Absolute Maximum Ratings

|   |                |
|---|----------------|
| V <sub>s</sub> to GND:                  | 6V             |
| Lead temperature soldering, 60 sec max: | 300°C          |
| Storage temperature:                    | -65°C to 150°C |
| Operating temperature:                  | -40°C to +85°C |

Miniature Amplifier PCB w/ optional ST60 (shown 3x actual size)

## Highlights

- Auto-zeroing operational amplifier on-board
- Several standard gain options available
- Low noise
- Temperature sensor on board
- Single power supply (2.7V – 5.5V)
- Low Power (1mA @ 5V)
- Voltage reference on board

## Miniature Amplifier PCB

### Typical Application

The diagram in Figure 1 shows the schematic of the ST60 detector connected to the board. The schematic has four main sections:  $S_1$ : thermopile detector,  $U_1$ : amplifier,  $U_2$ : voltage reference, and  $U_3$ : LM20 temperature sensor.

Figure 1. Amplifier schematic with gain of 1000

#### Amplified detector output Voltage range

Between  $V_{out}$  and GND: 0 to  $V_S$  (when detector package is at thermal equilibrium with target, zero volts detector output will produce 1.25V PCB output)

Between  $V_{out}$  and  $V_{ref}$ : Minimum output:  $-1.25V$ , Maximum output:  $V_S - 1.25V$  (when detector package is at thermal equilibrium with target, zero volts detector output will produce 0.0V PCB output)

**Detector Mounting Note:** Use Thermal Epoxy or Thermally Conductive Paste between top of LM20 and detector header

**LM20 versus Thermistor Note:**  $U_3$ ,  $R_1$  &  $C_1$  removed if thermistor is connected.

# Miniature Dual Amplifier PCB

## Applications

Facilitates fast R&D startup time that can be integrated into your prototypes or final system design.

- Non-contact Temperature measurement
- Gas analysis
- Human Presence Detection & Direction
- Multiplexing of a number of thermopiles
- Reduction of noise on long cables

## General Description

Available in three amplifier gain settings: 30, 50, and 1,000, this PCB includes a LM20 temperature sensor and 1.25V voltage reference. Although sized for dual channel TO-5 packages, this amplifier is electrically compatible with all of Dexter Research Center detectors, providing convenient buffering and pre-amplification of thermopile signal. The amplifier circuit board is impressively small (0.36" x 1.17") and is designed around the CS3012 amplifier with low offset (<10 μV), low drift (<0.05 μV/°C), and low bias current (50pA). The Mini Amp will operate on a 2.7V to 5.5V single supply.

The CS3012 dual amplifier is designed for precision amplification of low level signals and are ideally suited to applications that require very high closed-loop gains. These amplifiers achieve excellent offset stability, super-high open-loop gain, and low noise over time and temperature. The devices also exhibit excellent CMRR and PSRR. The common mode input range includes the negative supply rail.

The LM20 temperature sensor (National Semiconductor) has precision analog output. The transfer function of LM20 is predominantly linear, yet has slight predictable parabolic curvature. The accuracy of the LM20 when specified to a parabolic transfer function is 1.5°C at room temperature. There is an option to connect any two terminal temperature sensor in place of LM20, for example a thermistor.

The LT 1790 low drop out voltage reference combines high accuracy (0.05%) and low drift (10ppm/°C). The voltage reference has operational temperature range from -40°C to +85°C. The board may be used with an external voltage reference as well.

## Thermopile Comparison: Thin Film vs. Silicon

### Benefits: Thin Film Based Thermopile Detectors

- Higher Output and Sensitivity
- Lower Noise
- Higher S/N Ratio
- Lower Resistance
- Larger Active Area Available
- Greater Flexibility in Responsivity and Time Constant by selecting Back-Fill gas. See Application Brief 7.
- Proven Technology – In Production Since 1977

### Benefits: Silicon Based Thermopile Detectors

- Lower Temperature Coefficient of Responsivity
- Lower Cost (ST60 & ST150 models)
- Smaller Active Areas
- Faster Time Constant
- Response Linear for Higher Incident Power Levels (ST60 & ST150 models)
- Smaller Packages available
- Customizable Multi-Channel Configurations (ST60 & ST150 models)
- Adjustable Responsivity and Time Constant by selecting Back-Fill Gas.
- Proven Technology – In Production Since 1990

## Effects of Back-fill Gas on Thermopile Detectors

The selection of back-fill gas in a thermopile detector package affects three important performance parameters: the output voltage, Responsivity, and time constant. Different gases have different molecular thermal conductivity. The molecular thermal conductivity affects the thermal resistance of the detector and package, thereby affecting the output voltage, Responsivity, and time constant. Please note that there are other factors that affect these parameters such as: amount of black absorber, use of optional internal heat sink, type of package (cold weld vs. resistance weld), and thermopile model. The effect of the back-fill gas on these three parameters is less with Silicon Based Thermopiles than Thin Film Based Thermopile Detectors.

The specifications shown on the Dexter Research Center data sheets are for Argon or Nitrogen depending on detector model (see individual data sheets for gas specified, ST60/R (all models), ST150 (all models), SLA32, and SA32x32 data sheets are with N<sub>2</sub>, all others are with Ar). These parameters change by the same percentage, approximated by the Multipliers shown in Tables 1, 2, and 3, for Thin Film Based, "S" type Silicon Based, and "ST" type Silicon Based thermopiles respectively. For example, when a detector package is back-filled with Xenon instead of Argon, the output voltage, Responsivity, and time constant will increase by 2.4 times for Thin Film Based Thermopiles (see Table 1 below). Where as these parameters would increase 2.1 times for "S" type Silicon Based Thermopiles (see Table 2 below). See Table 4 for the backfill gas calculations for all of our detector models.

Dexter Research Center (DRC) offers four standard back-fill gas options: Ar, N<sub>2</sub>, Xe, and Ne. The effect varies for each gas depending on whether it is in a Thin Film, "S" type Silicon Based, or "ST" type Silicon Based Thermopile Detector. The tables below show a **rough approximation** of the back-fill gas factor (Multiplier) for these three groups of thermopile detectors. These tables are only intended to be a guide, the Multipliers below can vary by more than +/-25%. This variation is limited by the fact that if a Multiplier is greater than 1.0, then the multiplier can not go below 1.0 and if a Multiplier is less than 1.0, then the multiplier can not go above 1.0.

| <b>Thin Film Based Thermopile in Argon (Ar)</b> |            |
|---|------------|
| Gas   | Multiplier |
| Nitrogen (N <sub>2</sub> )                      | .75        |
| Xenon (Xe)                                      | 2.4        |
| Neon (Ne)                                       | .4         |

Table 1: Output voltage, Responsivity, and time constant Multipliers for Thin Film Based Thermopile detectors relative to Argon.

Two tables for Silicon Based Thermopiles are shown below: Table 2 is for "S" type Silicon Based models with data sheets using Argon (model S25, S60 and S707).

File: U:\DRC Library\DRC Templates & Forms\Website\WEB DOC\STechnical Briefs\6563 Rev B.doc

Update: 3/27/03

Table 3 is for “ST” type Silicon Based models with data sheets using Nitrogen (all ST60 and ST150 models including the multi-channel models). Currently, the model SLA32 and SA32x32 are only available with N<sub>2</sub> back-fill.

| “S” type Silicon Based Thermopile in Argon (Ar) |            |
|---|------------|
| Gas   | Multiplier |
| N <sub>2</sub>                                  | .87        |
| Xe  | ~1.6       |
| Ne  | 0.6        |

Table 2: Output voltage, Responsivity, and time constant Multipliers for “S” type Silicon Based Thermopile detectors relative to Argon.

| “ST” type Silicon Based Thermopile in Nitrogen (N <sub>2</sub> ) |            |
|--|------------|
| Gas  | Multiplier |
| Ar   | 1.1        |
| Xe   | 1.55       |
| Ne   | 0.9        |

Table 3: Output voltage, Responsivity, and time constant Multipliers for “ST” type Silicon Based Thermopile detectors relative to Nitrogen.

### 2M Time Constant Example

As an example of how the above back-fill gas Multipliers work, take the DRC model 2M. From the DRC data sheet for the 2M, the time constant is 85ms when back-filled with Argon.

To calculate the approximate time constant in Xenon, multiply the Argon time constant of 85ms by the Ar to Xe Multiplier of 2.4 (see Table 1) which gives 85ms x 2.4 = 204ms.

Therefore, by back-filling the model 2M with Xe, the time constant is approximately 204ms instead of 85ms when filled with Ar.

### 2M Output Voltage Example

The same holds true for the output voltage. From the DRC data sheet for the model 2M, the output voltage is 250µV when exposed to 330µW/cm<sup>2</sup> radiation and back-filled with Argon.

To calculate the approximate test stand output voltage for the 2M back-filled with Xenon, multiply the voltage of 250µV by the Ar to Xe Multiplier of 2.4 (see Table 1) which gives 250µV x 2.4 = 600µV.

Therefore, by back-filling the model 2M with Xe, the test stand output voltage is approximately 600µV instead of 250µV when back-filled with Ar. Table 4 below, shows the back fill gas calculations for all of our thermopile detector models.

### Thermopile Time Constant Determination

The time constant of thermopile detectors can be determined by several methods depending on the specific waveform of the radiation used to excite the detector. If the detector is subject to a step function of radiation, its response follows the function  $V_t = V_{\max}(1 - e^{-t/\tau})$ , where  $V_t$  is the detector output at any time  $t$ . The time constant ( $\tau$ ) of the system is defined as the time when  $V_t$  is 63.2% of its maximum static value  $V_{\max}$ .

If the detector is subjected to sinusoidally modulated radiation, its frequency response follows the function  $V_d = V_s[1 + (2\pi\tau/T)^2]^{-1/2}$ , where  $V_d$  is the dynamic amplitude of the detector output voltage at any wave period  $T$ , and  $V_s$  is the static amplitude of the output voltage generated by un-modulated radiation. The period  $T_o$ , at which the output amplitude  $V_d$ , falls off by 3dB (.707  $V_s$ ) from the static value, relates to the detector time constant by the expression  $\tau = T_o/k\pi$ , where  $k = 2$  for sinusoidally modulated signals.

The waveform of chopper-modulated radiation corresponds closely to a square wave, and in this case the coefficient  $k = 1.124$ . The same relationship between the time constant and sine or square wave modulated radiation was found by Jones (see reference below).

A Red LED may be used with either method if the thermopile window/filter transmits in the visible spectrum. The appropriate coefficient should be applied depending upon the waveform used. At Dexter Research Center (DRC), the time constant is determined using two methods. 1) If the thermopile window/filter transmits in the visible spectrum then DRC uses a square wave modulated Red LED. 2) If the thermopile window/filter does not transmit in the visible spectrum, then DRC uses a chopped blackbody.

Direct measurement of the approximate time constant with a modulated signal is relatively simple and quick. Adjust the peak-to-peak trace of the detector's DC output to seven divisions on an oscilloscope using a very slow modulation frequency. Increase the frequency until the peak-to-peak trace spans five divisions (.707 x 7div. = 4.95div.). This is approximately -3 dB of  $V_{\max}$ . The time constant can then be determined from the frequency or from the wave period, again using the appropriate coefficient for the waveform utilized.

## Package Hole Size and Aperture Options

Dexter Research offers a wide variety of package hole sizes and internal apertures which can be used to modify the Field of View (FOV) of single element detectors or minimize cross talk in multi-channel detectors.

### Package Hole Size

Package hole size can be customized to modify detector Field of View (FOV) of TO-5 packages. Hole size also defines the amount of energy coming into the package and subsequently falling on the detector active area. Package (cover) hole sizes available (inches): .100", .125", .150", .180", .202" dia.

FOV effects of cover hole size on single element detector (model 1M used for example).

### Internal Aperture

Internal apertures can be used to modify the FOV of our single element detectors in TO-5 packages.

Internal aperture sizes available (mm): .25mm, .5mm, .6mm, .75mm, 1.0mm, 1.5mm, 2mm dia.

Internal apertures for limiting cross talk in multi-element detectors are available for the following models: DR34, TM34, T34, DR46, 2M Quad, 10 channel. The aperture hole sizes are generally the same size as the detector active area.

FOV effects of internal aperture on single element detector (model 1M used for example).
