

iC-NZN

N-TYPE LASER DIODE DRIVER

Rev D1, Page 1/16

FEATURES

- ◆ Peak value controlled laser diode driver for operation from CW up to 155 MHz
- ◆ Spike-free switching of laser currents of up to 300 mA
- ◆ Setting of laser power (APC) via external resistor
- ◆ Optional current control (ACC)
- ◆ Laser current limitation
- ◆ LVDS/TTL switching input with TTL monitor output
- ◆ Low current consumption sleep-mode < 50 μ A
- ◆ Safety shutdown with overtemperature
- ◆ Error signal output with overtemperature, undervoltage and overcurrent
- ◆ All current LD types can be used (N/P/M configurations)
- ◆ Blue laser diodes supported
- ◆ Fast soft-start
- ◆ Strong suppression of transients with small external capacitors

APPLICATIONS

- ◆ Pulsed and CW laser diode modules
- ◆ Laser diode pointers
- ◆ Laser levels
- ◆ Bar-code readers
- ◆ Distance measurement
- ◆ Blue laser diodes

iC-NZN

N-TYPE LASER DIODE DRIVER

Rev D1, Page 2/16

DESCRIPTION

Laser diode pulse driver iC-NZN allows CW operation of laser diodes and spike-free switching with defined current pulses up to 155 MHz. The optical output power of the laser diode is set-up by means of an external resistor (RMD/PMD). For laser current control without a monitor diode, the laser current monitor at pin IMON is utilised. For high pulse frequencies the device can be switched into controlled *burst mode*. A previously settled operating point is maintained throughout the burst phase.

An averaging current monitor can be set by means of an external resistor at pin RSI. When the current limit is reached, overcurrent is signalled at NERR and the current from pin LDA is limited to the pre-set value but the iC is not shut down. There is an additional current limitation in pin LDK that prevents the iC from overpowering the laser diode.

Setting pin NSLP low, the iC enters a low consumption sleep-mode (< 50 µA typ.).

PACKAGING INFORMATION QFN24 4 mm x 4 mm to JEDEC

PIN CONFIGURATION

PIN FUNCTIONS

No. Name Function

1	VDD	Power Supply
2	AVG	Enable Averaging Control
3	MD	APC setup, monitor input
4	IMON	Laser Current Monitor
5	CID	Enable Pulldown Current at CI
6	EP	Positive LVDS/TTL switching input
7	EN	Negative LVDS switching input
8	TTL	Enable TTL input
9	VSYS	Sync Output Supply Voltage (connect to VDD or GND, if SYN is not used)
10	SYN	Sync Output
11	RGND	Reference Ground
12	RVDD	Reference (P-type laser diodes)
13	LDK	Laser Diode Cathode
14	AGND	Analog ground
15	CIS	Power Control Capacitor sense
16	CI	Power Control Capacitor
17	LDA	Laser Diode Anode
18		n/c
19	RSI	Current Monitor Setup
20	REGE	Control Enable
21	GND	Ground
22	NSLP	Not Sleep-Mode
23	NERR	Error Output
24		n/c

The *Thermal Pad* is to be connected to a Ground Plane (GND) on the PCB.

Only pin 1 marking on top or bottom defines the package orientation (© NZN label and coding is subject to change).

Figure 2: Laser current pulse

iC-NZN

N-TYPE LASER DIODE DRIVER

Rev D1, Page 8/16

DESCRIPTION OF FUNCTIONS

iC-NZN is a laser diode pulse driver. The device features the following functions:

- Peak or averaging control
- Optical power (APC) or current control (ACC)
- Pulses of up to 155 MHz in controlled *burst mode*
- Laser current limitation
- Operation of blue laser diodes possible
- Error signalling for overcurrent
- Sleep mode with less than 50 µA consumption

OPTICAL POWER CONTROL

The iC-NZN supports the control of the laser diode's optical output power for all common laser diode pin configurations (N, P and M). The control is enabled with pin REGE set to high. With AVG set to low, the peak power control is enabled. The laser power level is selected by means of the resistor RMON (= RMD +

PMD). This control mode can be used for frequencies up to ca. 4 Mhz. For higher frequencies the averaging control (AVG = high) or the *burst mode* have to be used. Tables 4 and 5 show how to set the inputs for laser control depending on the input interface selected (TTL or LVDS).

Laser control in TTL mode (TTL = high/open)					
EP	EN	NSLP	REGE	SYN	Mode
-	-	low/open	-	-	Power-save mode
low/open	open	high	-	low	LDA charged, laser off
high	open	high	high/open	high	LDA charged, laser on, peak control
high	open	high	low	high	LDA charged, laser on, burst mode

Table 4: Laser control in TTL mode

Laser control in LVDS mode (TTL = low)					
EP	EN	NSLP	REGE	SYN	Mode
-	-	low/open	-	-	Power-save mode
< EN	> EP	high	-	low	LDA charged, laser off
> EN	< EP	high	high/open	high	LDA charged, laser on, peak control
> EN	< EP	high	low	high	LDA charged, laser on, burst mode

Table 5: Laser control in LVDS mode

RMON dimensioning

Peak control (AVG = low): In order to calculate the right value of RMON, the value of *IM* (monitor current with respect to optical output power) of the laser diode must be known. RMON must be chosen in a way that the monitor current generated by the desired output power creates a voltage drop across RMON of 500 mV (cf. Electrical Characteristics No. 201).

Control modes		
Averaging	Operation mode	RMON calculation
AVG = 0	Peak control	$RMON = \frac{V(MD)}{IM}$
AVG = 1	Averaging control	$RMON = \frac{V(MD)}{IM \times D}$

Table 6: RMON dimensioning

Averaging control (AVG = high): In this mode the calculation is the same as in peak control, only the result has to be divided by the duty cycle of the laser pulses, $D = \frac{t}{T}$. At a duty cycle of e.g. 50% $D = \frac{1}{2}$. This requires an external averaging capacitor of sufficient size at pin CI though.

Example

By way of example, an output level of 1 mW is to be set. With an optical power of 1 mW e.g. laser diode HL6339G has a typical monitor current (*IM*) of 15 µA. The following value is then obtained for the resistor at pin MD (RMON = PMD + RMD, where RMD is a fixed resistor and PMD a potentiometer.):

iC-NZN

N-TYPE LASER DIODE DRIVER

Rev D1, Page 9/16

$$R_{MON} = \frac{V(MD)}{I_M} = \frac{0.5 \text{ V}}{15 \mu\text{A}} = 33.34 \text{ k}\Omega$$

External capacitor mode

In applications where an external capacitor is required (see *best performance recommendations* below), the external capacitor mode must be enabled (pin CID = high). This connects the capacitor to the control circuit and additionally enables a pull-down current at pin CI to prevent this capacitor from being charged due to residual currents (cf. Electrical Characteristics No. 406).

Best performance recommendations

The operating point for the laser diode is stored in an on-chip capacitor. This permits a fast start-up but can

lead to an unstable control circuit under certain conditions such as inadequate PCB layout or laser diodes with very low monitor current. In these cases, an optional capacitor can be connected as close as possible to the chip, across pin CI and CIS. This will prevent instability of the control circuit. For averaging control a 10 nF capacitor at CI is recommended. Special care must be taken in PCB layout when laying out the path from the laser diode's cathode via pin LDK to AGND. This path must be kept as short as possible to avoid parasitic inductances. A *snubber network* across the laser diode helps to compensate for these parasitic inductances.

Figures 3, 4 and 5 show the typical set-up for the different N, P and M-type diode configurations.

N-type diodes

Figure 3: Circuit example for N-type laser diodes

P-type diodes

Although this kind of laser diodes are supported by iC-NZN, it's strongly recommended to use iC-NZP instead since in this configuration, all the pulses at LDK will be coupled directly to pin MD due to monitor diode's

internal capacitance, thus making an accurate control much more difficult. Moreover, applications with P-type laser diode case grounded are possible with iC-NZP only.

iC-NZN N-TYPE LASER DIODE DRIVER

Rev D1, Page 10/16

Figure 4: Circuit example for P-type laser diodes.

M-type diodes

Figure 5: Circuit example for M-type laser diodes

Although this type of laser diode are supported by iC-NZN, it's strongly recommended to use iC-NZP instead since in this configuration, all the pulses at LDK will be coupled directly to pin MD due to monitor diode's

internal capacitance, thus making an accurate control much more difficult. Moreover, applications with M-type laser diode case grounded are possible with iC-NZP only.

iC-NZN

N-TYPE LASER DIODE DRIVER

Rev D1, Page 11/16

LASER CURRENT LIMITATION

Figure 6: iC-NZN LDA current limitation

iC-NZN features two different current limitations, limiting the average current flowing from pin LDA plus the current flowing into pin LDK.

LDA current limitation

iC-NZN monitors the average laser current flowing from pin LDA (Figure 6). The DC current limit is set by means of a resistor at pin RSI.

When dimensioning resistor RSI the following applies (cf. Electrical Characteristics No. 106):

$$I_{max}(LDA) = 540 \times \frac{0.52 V}{RSI}$$

Short pulses at LDA with higher currents are possible as only the DC current is monitored and capacitor CLDA supplies the current for short pulses.

LDK current limitation

The control circuit also monitors the laser current in pin LDK and limits this current when reaching the threshold also defined by RSI. The following applies (cf. Electrical Characteristics No. 107):

$$I_{max}(LDK) = 700 \times \frac{0.52 V}{RSI}$$

BURST MODE

In *controlled burst mode* iC-NZN can pulse with up to 155 MHz. *Controlled* here means that a pre-set operating point is maintained during the *burst phase*.

Therefore an operating point is settled first, for which pin REGE has to be high and the laser diode must be switched on. Once the operating point has been reached the laser diode can be switched off again. The operating point is stored in an on-chip capacitor and when pin REGE is set to low, the *burst mode* is activated. The pre-set operating point is maintained.

For a longer burst mode, an external capacitor can be connected to pin CI. To prevent the laser current from rising due to residual currents, the capacitor is discharged then with a maximum of 2.6 μA (cf. Electrical Characteristics No. 406). As the capacitor is discharged gradually, the output level must be re-settled again after a certain period, depending on the admissible degradation of the laser output power.

Rev D1, Page 12/16

The iC-NZN also supports laser current control, when no monitor diode is present. For that purpose, a fraction of the current flowing through the laser diode is provided at IMON pin (ILDK / 240, cf. Electrical Characteristics No. 407).

The laser current is set by means of resistor RMON (= RMD + PMD).

$$R_{MON} = \frac{V(RVDD) - V(MD)}{I_{MON}}$$

Figure 7 shows the typical set-up for current control.

External capacitor mode

In applications where an external capacitor is required (see *best performance recommendations* below), the external capacitor mode must be enabled (pin CID = high). This connects the capacitor to the control circuit and additionally enables a pull-down current at pin

CI to prevent this capacitor from being charged due to residual currents (cf. Electrical Characteristics No. 406).

Best performance recommendations

The operating point for the laser diode is stored in an on-chip capacitor. This permits a fast start-up but can make the regulated system unstable under certain conditions such as inadequate PCB layout. In these cases, an optional capacitor can be connected as close as possible to the chip, across pins CI and CIS.

Setting AVG to hi, keeps the control loop always on and settled, thus improving the dynamic performance.

Special care must be taken in PCB layout when laying out the path from the laser diode's cathode via pin LDK to AGND. This path must be kept as short as possible to avoid parasitic inductances. A *snubber network* across the laser diode also helps to compensate for these parasitic inductances.

Figure 7: Example set-up for current control

iC-NZN

N-TYPE LASER DIODE DRIVER

Rev D1, Page 13/16

BLUE LASER DIODES

With the iC-NZN also blue laser diodes can be driven. Due to the high forward voltage of these laser diodes, an appropriate supply voltage must be provided. The current limitation at pin LDA cannot be used then, since only pin LDK is capable of handling the higher voltage

required for the blue laser diodes. Nevertheless, the current limitation protection in pin LDK (cf. Electrical Characteristics No. 107) is still active. Figure 8 shows a typical set-up for blue laser diodes with APC and figure 9 with ACC.
